

Prevention of Dementia?

THE LANCET

Volume 396, Number 10248, Pages 413-446, August 5, 2020 www.thelancet.com

"It is never too early and never too late in the life course for dementia prevention."

Gill Livingston @ gill_livingston

What I will talk about

- Why should we consider dementia as preventable
- Lifecourse risk
- Discussion of individual risk factors
- Modification of risk
- What should we do?

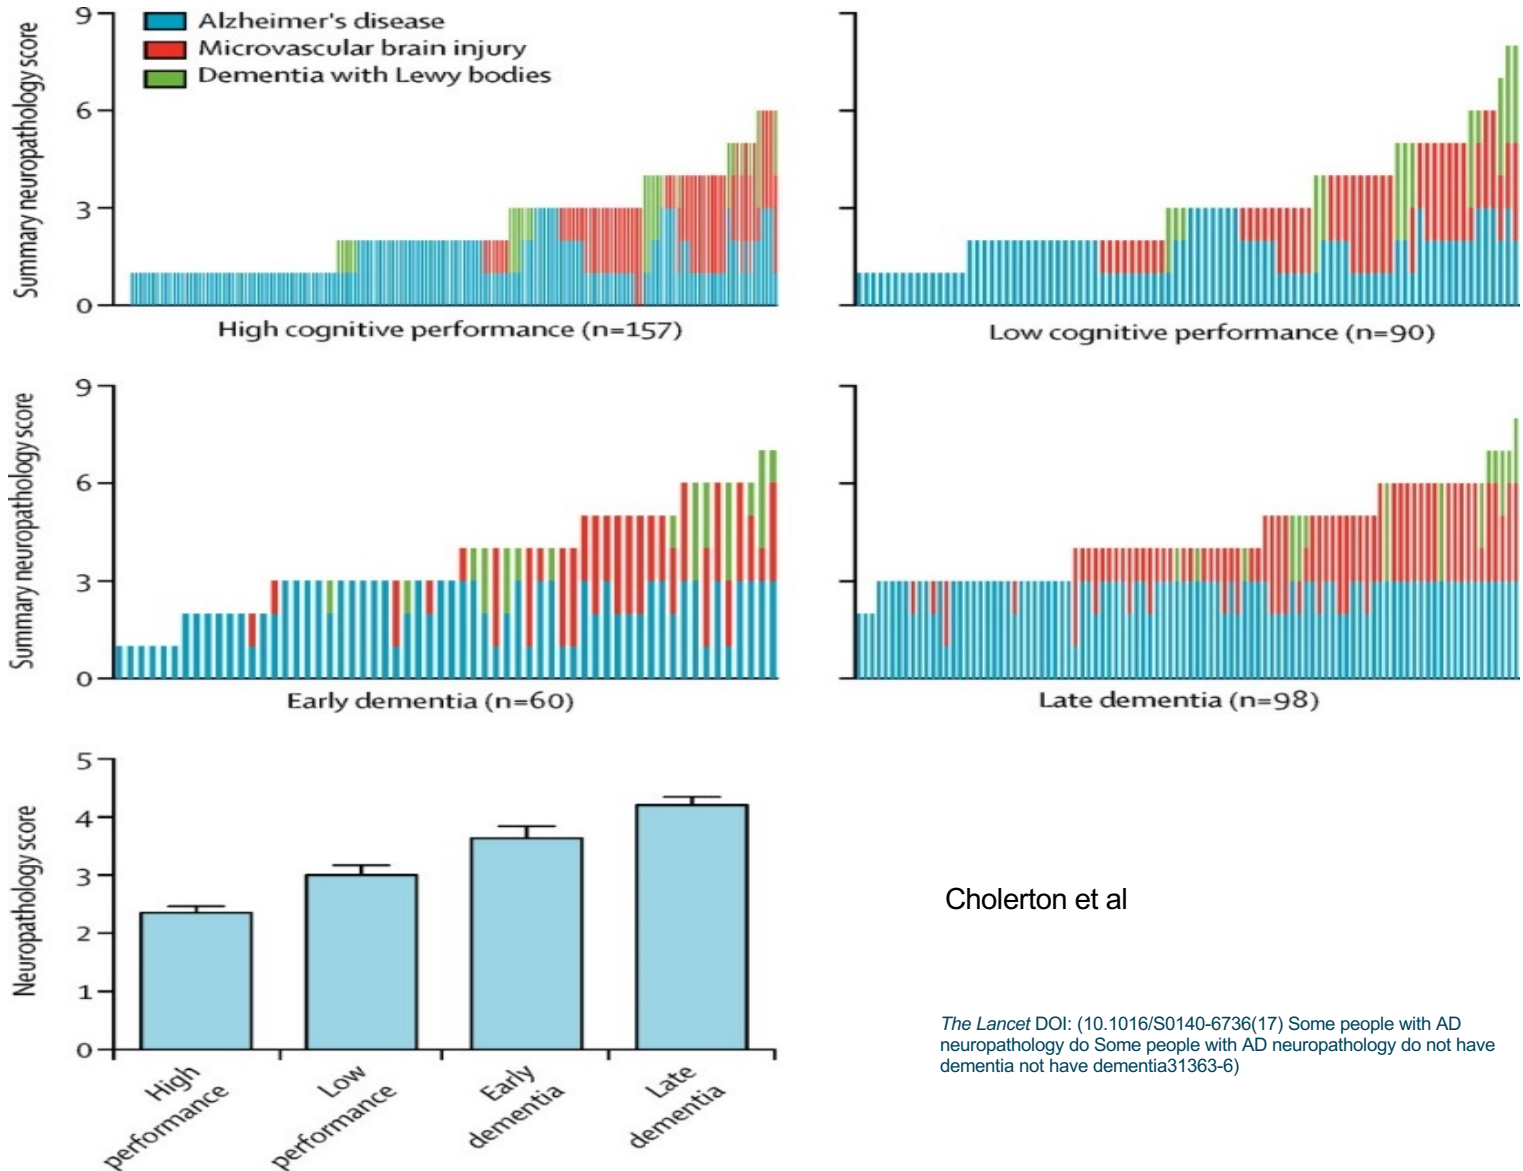

Why consider dementia preventable

↑dementia as ↑ older people – 50 →132 million by 2050.
Particularly in LMIC

- 25% incidence decrease in past 20 years; US and Europe
- Stable or increased in some countries -Japan, South Korea, Hong Kong, Brazil, India and Taiwan
 - So dementia is potentially not inevitably preventable
- Mechanisms thought to be
 - Cognitive reserve
 - Reduction in damage
- Improvements
 - higher income, more educated people within HIC.
 - Men > woman (24 vs 8%)

Some people with neuropathology do not have dementia

Cholerton et al

The Lancet DOI: (10.1016/S0140-6736(17)31363-6) Some people with AD neuropathology do not have dementia

Twelve risk factors

Early life

- Less education

Mid life (45-65)

- Peripheral hearing loss
- Hypertension
- Obesity
- Traumatic Brain Injury
- Excessive alcohol

Late life (>65)

- Smoking
- Depression
- Physical inactivity
- Air Pollution
- Social isolation
- Diabetes

PAF calculation

- Population Attributable Fraction
- Fraction theoretically prevented by eliminating risk factor
- $PAF = \text{Relative Risk (meta-analysis)} \times \text{Prevalence of risk factor}$
- Used all-cause dementia
- International data when available
- Twelve risks
- We know there are others

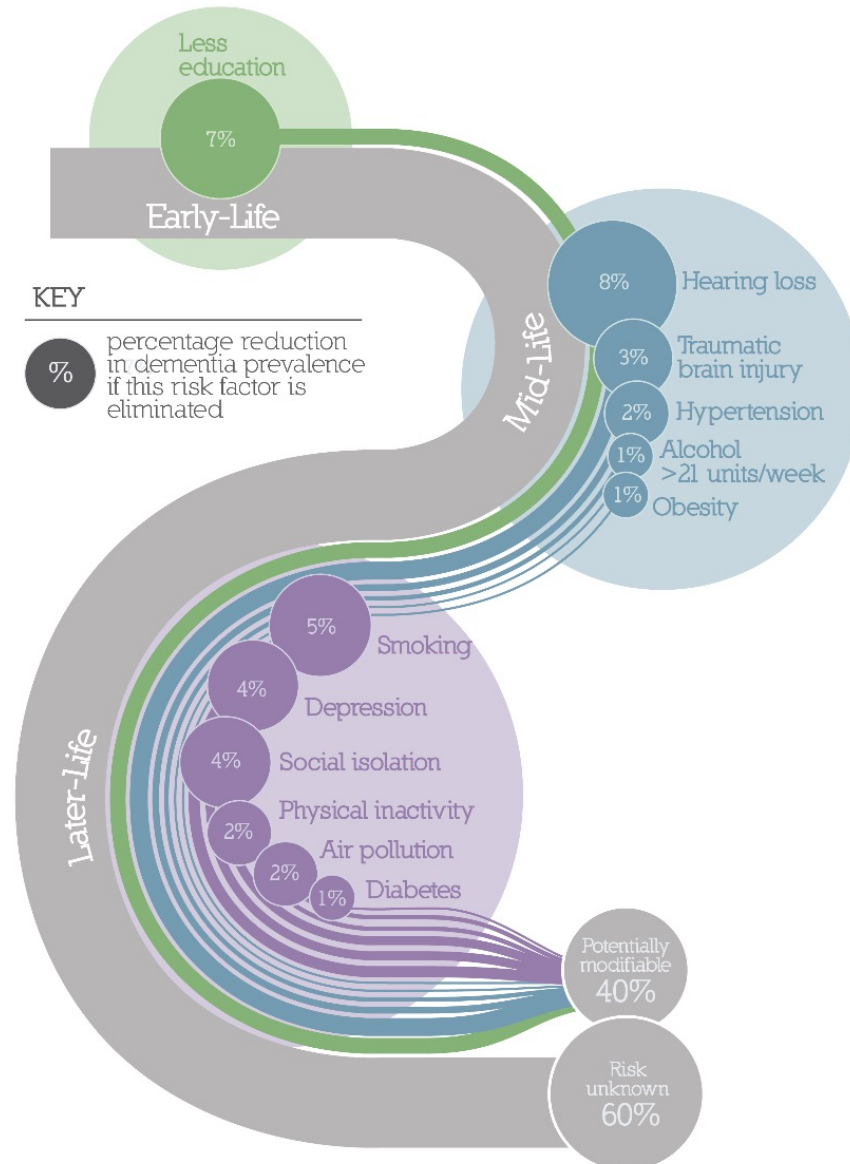

Communality –people not lab rats

People tend to have clusters of risk factors

- Input data on all risk factors
- Calculate tetrachoric correlation to generate correlation matrix
- Conduct principal-component analysis on the matrix to generate eigenvectors (directions mapped onto the datapoints from which variance to the data is measured)
- unobserved factors underlying the variables that explain the variance
- Retain components with eigenvalues ≥ 1 in model
- Communality is the sum of the square of all factor loadings (how much each unobserved component explained each measured variable)
- Weighting (1-communality)
- Individual risk factor PAF = $P_e (RRe-1) / [1 + P_e (RRe-1)]$

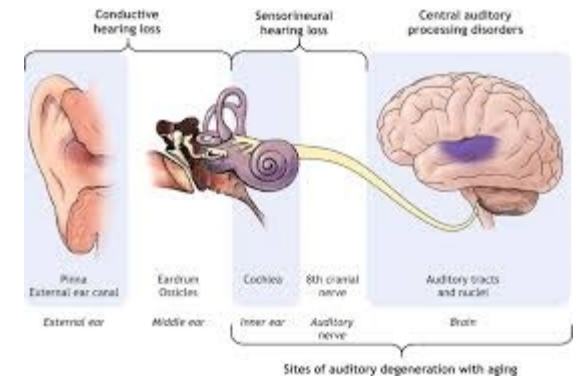

Population Attributable Fraction- 40%

Risk factor	Relative Risk for dementia	Risk factor prevalence	Communality (%)	Unweighted PAF (%)	Weighted PAF* (%)
Early life (<45)					
Less education	1.6 (1.3 -2.0)	40.0	61.2	19.4	7.1
Mid -life (age 45 -65)					
Hearing loss	1.9 (1.4 -2.7)	31.7	45.6	22.2	8.2
Traumatic brain injury	1.8 (1.5 -2.2)	12.1	55.2	9.2	3.4
Hypertension	1.6 (1.2 -2.2)	8.9	68.3	5.1	1.9
Alcohol >21units/week	1.2 (1.1 -1.3)	11.8	73.3	2.1	0.8
Obesity (Body Mass Index ≥30)	1.6 (1.3 -1.9)	3.4	58.5	2.0	0.7
Later life (age >65)					
Smoking	1.6 (1.2 -2.2)	27.4	62.3	14.1	5.2
Depression	1.9 (1.6 -2.3)	13.2	69.8	10.6	3.9
Social isolation	1.6 (1.3 -1.9)	11.0	28.1	4.2	3.5
Physical inactivity	1.4 (1.2 -1.7)	17.7	55.2	9.6	1.6
Diabetes	1.5 (1.3 -1.8)	6.4	71.4	3.1	1.1

Hearing loss

- High quality papers
 - FU ≥ 5 years,
 - objective measure peripheral hearing (pure-tone audiometry)
 - Outcome incident dementia adjusted for age & CV risk

Study	RR	95%-CI	W(random)
Lin 2011	2.32	[1.32; 4.07]	27.3%
Gallacher 2012	2.67	[1.38; 5.17]	21.3%
Deal 2016	1.55	[1.10; 2.19]	51.4%
Random effects model	1.94	[1.38; 2.73]	100%

Heterogeneity: I-squared=29%, tau-squared=0.0278, p=0.2445

Hearing- highest PAF

- 3,777 people aged ≥ 65 with self-reported hearing problems- \uparrow dementia incidence 25-year later except if using hearing aids (Amieva et al 2017).
- 2114 hearing impaired MCI (mean age 78). Using hearing aids \rightarrow \downarrow dementia risk (HR= 0.73). Mean time to dementia 2 vs 4 years (Bucholic et al 2021)
- 3811/7385 people hearing loss (mean age 65). \downarrow cognition when not using hearing aids. (Ray et al 2018)
- National representative survey of 2040 people aged >50 , tested two-yearly for 18 years
 - Hearing aid biggest protection from cognitive decline. Maharani et al 2018
- Hearing loss associated temporal lobe volume loss

Education and cognitive stimulation

- Education is important for cognitive reserve.
- Education till age 20 is additionally protective

- People with cognitively stimulating vs non-stimulating jobs ~20% ↓dementia risk.
- Cognitive stimulation at work associated with ↓proteins that inhibit central nervous system axonogenesis & synaptogenesis
- Lower levels of these proteins also associated with lower dementia risk.

- Kivimaki et al 2021 BMJ

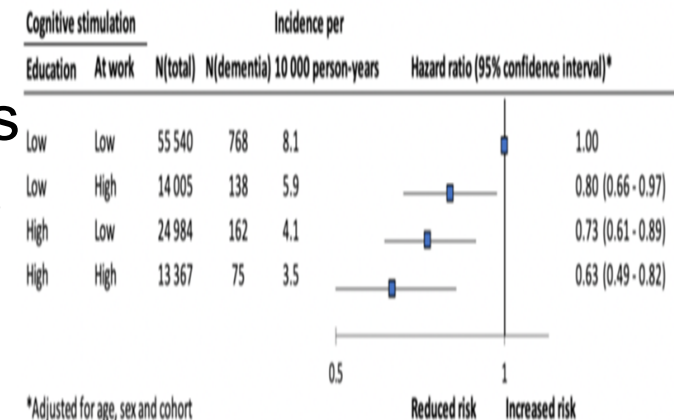

Figure 4. Association of lifecourse cognitive stimulation with incident dementia (a post hoc analysis)

- Some evidence that retirement may increase deterioration even allowing for ill health

Smoking

- Smoking
 - leads to cardiovascular pathology,
 - Cigarette smoke contains neurotoxins
- High prevalence contributes to the high PAF.
- Interventions to reduce cigarette smoking, which is declining in most countries;
- However smoking increasing in China, Middle East, south Asia and Africa
- Passive smoking also a risk
- Probably late life as more time smoking =more risk

Social contact

- PAF similar to HBP and inactivity.
 - ↑cognitive reserve and ↑ beneficial behaviours
- Dementia risk compared with married- 812000 people
 - ↑lifelong single (RR 1.4; 1.1-1.9), ↑Widow/ers (RR 1.2; 1.0-1.4)
- 28-year follow-up of 10,308 people
- ↑ social contacts age 60 years → ↓dementia risk (also 50 and 40)
 - (adjusted HR one SD social contact frequency 0.9 (0.79, 0.98), $p=0.02$),
- High social contact (102K) associated with better late-life cognitive function ($r=0.05$, 95% CI: 0.04–0.065)
- Studies >10 years good social engagement ↓dementia (n=8876, RR=0.9, 95% CI 0.8–1.0).
 - Penninkilampi et al 2018, Evans et al 2019, Sommerlad et al 2018.19

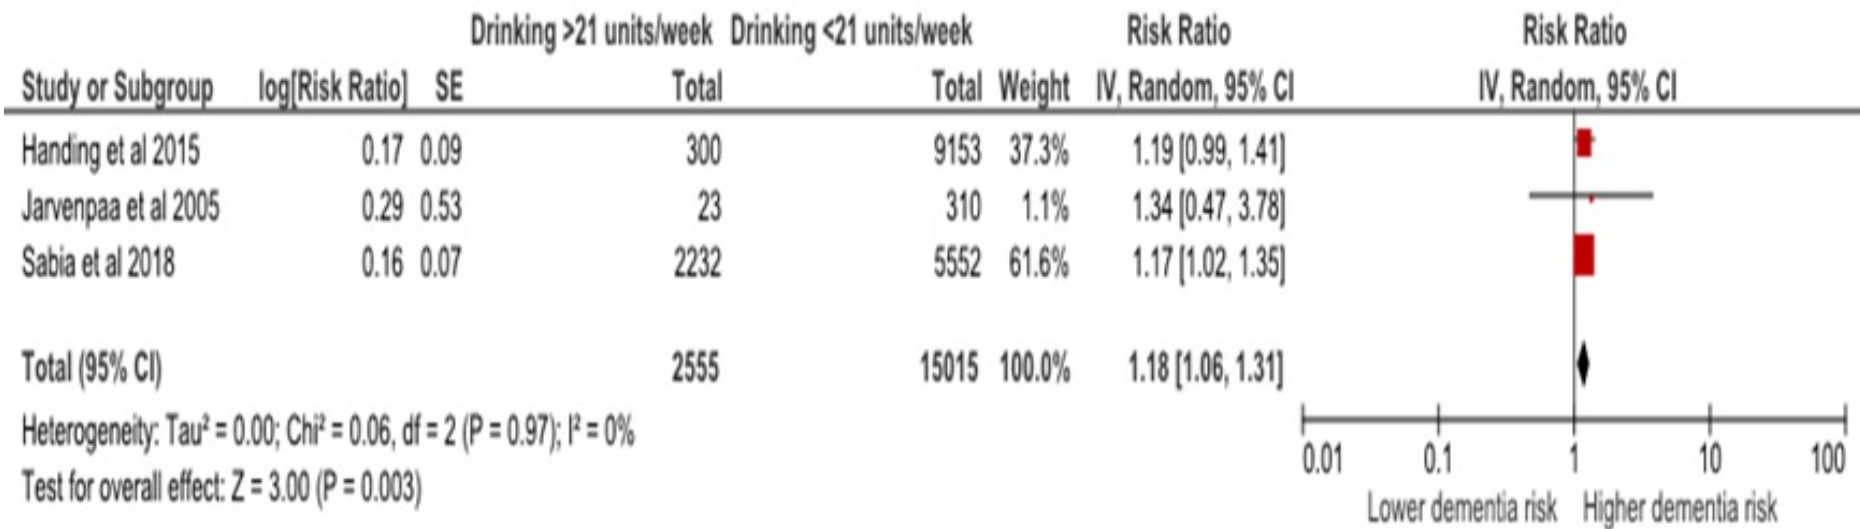

Hypertension

- Persistent mid-life hypertension increases risk of late life dementia (18-year FU HR= 1.6)
- Falling BP without intervention in later life may be caused by dementia development (HR 2.4).
- SPRINT MIND aiming to decrease systolic BP to <120 (control 140) in 9361 people aged 50+ without diabetes
- Five years later significant ↓MCI HR = 0.8, and combined MCI or dementia (HR, 0.9)
 - JAMA. 2019;321(6):553-561

Alcohol

- Heavy drinking effects the brain
- Non-linear effect: ↑dementia risk drinking **>21 UK units/week alcohol** (14 US drinks) vs <14 (10 here) . New meta-analysis RR =1.18

Traumatic Brain Injury

- TBI -car, motorcycle, bike injuries; military incidents, recreational sports, firearms & falls
- Risk ↑↑most in first 6 months but↑ over 30 years.
- Risk ↑with severity and number of TBI
- New meta-analysis. **TBI & all dementia RR 1.84**

Air pollution

- 13 longitudinal studies with 1-15 years follow-up of air pollutants exposure and incident dementia
- Exposure to PM_{2.5}, NO₂, and CO all ↑ dementia risk
- Too heterogeneous for meta-analysis
- Data from only study of all-cause air pollution and all cause dementia N=2,066,639; baseline mean age =67
- Canada pollutant concentrations among world lowest
- We calculated RR of dementia for those in the 3 highest quartiles compared to 4th = **1.09;1.07-1.11**
- Chinese longitudinal survey that Clean Air Act implementation mitigates cognitive decline (difference MMSE 2.45 points/4 years) Yao Yao et al 2022. TLHL

The Lancet commissions about diet

- Pattern of risk and the individual's other health, both physical and mental might be especially important.
- A Mediterranean or Scandinavian diet might help prevent cognitive decline in people with intact cognition,
 - particularly as one component of a healthy lifestyle,
 - although how long the exposure has to be
 - or at what age is unclear.

We do not recommend

- vitamins, oils or dietary supplements to prevent dementia
- extensive trials has not led to signals of benefit

Is the risk the same for everyone?

- Cohort studies primarily
 - White participants
 - High income countries
 - Risk varies between countries
 - Risk factors cluster around inequalities
 - Minority ethnic groups
 - Lower socio-economic groups
 - LMIC

Not just about individual intervention

- Culture, poverty and inequality are obstacles to, or drivers of, the need for change.
- Those who are most deprived need the changes most and will derive the highest benefit.
- As societies we need to think beyond promoting individual health and begin to improve circumstances in which people live

RCTs to prevent dementia

WORLD WIDE FINGERS

- FINGER RCT - 2-year Finnish multidomain intervention to prevent cognitive decline and dementia. 1260 people age 60–77 with CV risks
 - small reduction in cognitive decline vs control
- Healthy Ageing Through Internet Counselling in the Elderly (HATICE) - 18 months, 2724 people ≥ 65
 - Small improvement in CV primary outcome Vs control mainly through weight loss, and the dementia risk
 - Larger effect in younger age group (65–70 years) and those with less education, higher risk.
 - Targeting high-risk populations might be more effective

United States

- Laura Gitlin invited to give Lancet evidence to US congress end 2020
- **US congress** The National Alzheimer's Project Act (NAPA) Advisory Council create and advance a National Plan to address Alzheimer's disease and related dementias
- Added new goal (in 2021) to Reduce the Burden of Risk Factors
- To aggressively address 10 potential risk factors (↓15% by 2030)
- **CDC** consulted in 2021 on making a US policy with targets of the risk factors on prevention
- 15% per decade = ↓1.2 million people with AD in 2050

Be ambitious about prevention

- Aim for systolic BP ≤ 130 mmHg from around age 40
- Encourage hearing aids for hearing loss. \downarrow hearing loss
- Reduce exposure to air pollution & second-hand smoke.
- Prevent head injury
- Limit alcohol -drink < 14 AU units (21 UK) weekly
- Avoid smoking uptake & support smoking cessation
- Give all children with primary & secondary education.
- Reduce obesity and the linked condition of diabetes

Most vulnerable stand to gain most

Thank you
